Part I

CENTRAL CONCEPTS IN FAMILY THERAPY
Chapter 1

GOALS OF FAMILY THERAPY ACROSS THE LIFECYCLE

Family therapy is a broad term given to a range of methods for working with families with various biopsychosocial difficulties. Within the broad cathedral of family therapy there is a wide variety of views on what types of problems are appropriately addressed by family therapy; who defines these problems; what constitutes family therapy practices; what type of theoretical rational underpins these practices; and what type of research supports the validity of these practices.

Some family therapists argue that all human problems are essentially relational and so family therapy is appropriate in all instances. Others argue that marital and family therapy are appropriate for specific relationship problems or as an adjunct to pharmacological treatment of particular conditions, such as schizophrenia.

Some family therapists argue that problems addressed in therapy are defined by clients, that is, parents, children or marital partners seeking help. Others argue that problems are best defined by professionals in terms of psychiatric diagnoses or statutory status, such as being a family in which child abuse has occurred and on an at-risk register, or being a person with an alcohol problem on probation.

With respect to practices, some family therapists invite all family members to all therapy sessions. Others conduct family therapy with individuals, by empowering them to manage their relationships with family members in more satisfactory ways. Still others have broadened family therapy so that it includes members of the wider professional and social network around the family, and may refer to this approach as ‘systemic practice’.

There are many theories of family therapy. Some focus on the role of the family in predisposing people to developing problems or in precipitating their difficulties. Others focus on the role of the family in problem maintenance. But all family therapists highlight the role of the family in problem resolution. There is also considerable variability in the degree to which theories privilege the role of family patterns of interaction, family belief systems and narratives, and historical contextual and constitutional factors in the aetiology and maintenance of problems.
With respect to research, some family therapists argue that case studies or descriptive qualitative research provides adequate support for the efficacy of family therapy. On the other hand, some family therapists highlight the importance of quantitative results from controlled research trials in supporting the degree to which family therapy is effective in treating specific problems.

Within this volume, an integrative and developmental approach will be taken to family therapy, and where better to start than with a consideration of family problems across the lifecycle. Family problems occur across all stages of the lifecycle. Here are some examples:

- A six-year-old child whose parents cannot control him and who pushes his sister down the stairs.
- A 13-year-old girl who worries her parents because she will not eat and has lost much weight.
- A 19-year-old boy who believes he is being poisoned and refuses to take prescribed antipsychotic medication.
- A couple in their mid-30s who consistently argue and fight with each other.
- A blended family in which the parents have both previously been married and who have difficulties managing their children’s unpredictable and confusing behaviour.
- A family in which a parent has died prematurely and in which the 13-year-old has run away from home.
- A family in which a child is terminally ill and will not follow medical advice.
- A family with traditional values in which a teenager ‘comes out’ and declares that he is gay.
- A family in which both parents are unemployed and who have difficulty managing their children without getting into violent rows.
- A black family living in a predominantly white community, where the 16-year-old boy is involved in drug abuse in a delinquent peer group.

These are all complex cases that involve or affect all family members to a greater or lesser degree. A number of these cases also involve or affect members of the community in which the family lives. In some of the cases listed, other agencies, including schools, hospitals, social services, law enforcement, juvenile justice or probation, may be involved. Family therapy is a broad psychotherapeutic movement that offers conceptual frameworks for making sense of complex cases such as those listed here and entails approaches to clinical practice for helping families resolve complex problems.

The lifecycle is a particularly useful framework within which to conceptualise problems that may be referred for family therapy. In this chapter, normative models of the family and individual lifecycles will be
described. Gender development; lifecycle issues unique to lesbian and gay people; and issues of culture and class will also be discussed. The aim of the chapter is to sketch out some of the problem areas that may be addressed by family therapy across the lifecycle.

THE FAMILY LIFECYCLE

Families are unique social systems insofar as membership is based on combinations of biological, legal, affectional, geographic and historical ties. In contrast to other social systems, entry into family systems is through birth, adoption, fostering or marriage and members can leave only by death. Severing all family connections is never possible. Furthermore, while family members fulfil certain roles, which entail specific definable tasks such as the provision of food and shelter, it is the relationships within families which are primary and irreplaceable.

With single-parenthood, divorce, separation and remarriage as common events, a narrow and traditional definition of the family is no longer useful (Parke, 2004; Walsh, 2003a). It is more expedient to think of a person’s family as a network of people in the individual’s immediate psychosocial field. This may include household members and others who, while not members of the household, play a significant role in the individual’s life. For example, a separated parent and spouse living elsewhere with whom a child has regular contact; foster parents who provide relief care periodically; a grandmother who provides informal day-care, and so forth. In clinical practice the primary concern is the extent to which this network meets the individual’s needs.

Leaving Home

Having noted the limitations of a traditional model of family structure, paradoxically, the most useful available models of the family lifecycle are based on the norm of the traditional nuclear family with other family forms being conceptualised as deviations from this norm (Carter & McGoldrick, 1999). One such model is presented in Table 1.1. This model delineates the main developmental tasks to be completed by the family at each stage of development. In the first two stages, the principal concerns are with differentiating from the family of origin by completing school, developing relationships outside the family, completing one’s education and beginning a career. Problems in developing emotional autonomy from the family of origin may occur at this stage and may find expression in many ways, including depression, drug abuse and eating disorders such as anorexia and bulimia. Problems in developing economic independence may also occur where young adults have not completed their education or

where limited career options are available. In these circumstances some young adults become involved in crime.

**Forming a Couple**

In the third stage of the family lifecycle model, the principal tasks are those associated with selecting a partner and deciding to marry or co-habit. In the following discussion, the term marriage is used to cover both traditional marriage or the more modern arrangement of long-term co-habitation. Adams (1995) views mate selection as a complex process that involves four stages. In the first phase, partners are selected from among those available for interaction. At this stage, people select mates who are physically attractive and similar to themselves in interests, intelligence, personality and other valued behaviours and attributes. In the second phase, there is a comparison of values following revelation of identities through self-disclosing conversations. If this leads to a deepening of the original attraction then the relationship will persist. In the third phase, there is an exploration of role compatibility and the degree to which mutual empathy is possible. Once interlocking roles and mutual empathy have developed the costs of separation begin to outweigh the difficulties and tensions associated with staying together. If the attraction has deepened sufficiently and the barriers to separation are strong enough, consolidation of the relationship occurs. In the fourth and final phase, a decision is made about long-term compatibility and commitment. If a positive decision is reached about both of these issues, then marriage or long-term cohabitation may occur. When partners come together they are effectively bringing two family traditions together, and setting the stage for the integration of these traditions, with their norms and values, rules, roles and routines into a new tradition. Decision making about this process is not always easy, and couples may come to a marital and family therapist to address this complex issue.

**Marriage**

In the fourth stage of the family lifecycle model, the childless couple must develop routines for living together that are based on a realistic appraisal of the other's strengths, weaknesses and idiosyncrasies rather than on the idealized views (or mutual projections) which formed the basis of their relationship during the initial period of infatuation. Coming to terms with the dissolution of the mutual projective system, which characterizes the infatuation so common in the early stages of intimate relationships, is a particularly stressful task for many couples and may lead to a referral for marital or family therapy (Savage-Scharff & Bagini, 2002).
Contextual Factors Associated with Marital Satisfaction

The following demographic factors are associated with marital satisfaction (Newman & Newman, 2003):

- high level of education
- high socioeconomic status
- similarity of spouses interests, intelligence and personality
- early or late stage of family lifecycle
- sexual compatibility
- for women, later marriage.

The precise mechanisms linking these factors to marital satisfaction are not fully understood. However, the following speculations seem plausible. Higher educational level and higher socioeconomic status probably lead to greater marital satisfaction because where these factors are present people probably have better problem-solving skills and fewer chronic life stresses, such as crowding. Although there is a cultural belief that opposites attract, research shows that similarity is associated with marital satisfaction, probably because of the greater ease with which similar people can empathise with each other and pursue shared interests. Marital satisfaction drops during the child-rearing years and satisfaction is highest before children are born and when they leave home. During these periods, it may be that greater satisfaction occurs because partners can devote more time and energy to joint pursuits and there are fewer opportunities for conflict involving child management. Most surveys find wide variability in the frequency with which couples engage in sexual activity but confirm that it is sexual compatibility rather than frequency of sexual activity that is associated with marital satisfaction. Couples may come to marital and family therapy to find ways to cope with marital dissatisfaction and sexual difficulties, often arising from incompatibility.

Belief Systems and Interactional Patterns Associated with Marital Satisfaction

Studies of belief systems and interaction patterns of well-adjusted couples show that they have distinctive features (Gottman & Notarius, 2002; Gurman & Jacobson, 2002). These include:

- respect
- acceptance
- dispositional attributions for positive behaviour
- more positive than negative interactions
- focusing conflicts on specific issues
- rapidly repairing relationship ruptures
- addressing needs for intimacy and power.
Well-adjusted couples attribute their partners’ positive behaviours to dispositional rather than situational factors. For example, ‘She helped me because she is such a kind person’, not ‘She helped me because it was convenient at the time’. The ratio of positive to negative exchanges has been found to be about five to one in happy couples (Gottman, 1993). Even though well-adjusted couples have disagreements, this is balanced out by five times as many positive interactions. When well-adjusted couples disagree, they focus their disagreement on a specific issue, rather than globally criticising or insulting their partner. This type of behaviour is a reflection of a general attitude of respect that characterises happy couples. Well-adjusted couples tend to rapidly repair their relationship ruptures arising from conflict and they do not allow long episodes of non-communication, sulking or stonewalling to occur. Sometimes well-adjusted couples resolve conflicts by agreeing to differ. The specific process of agreeing to differ reflects a general attitude of acceptance.

Distressed couples, in contrast, have difficulties in many of the areas listed above and these may find expression in disagreements about communication and intimacy on the one hand; and the power balance or role structure of the relationship on the other. With respect to intimacy, usually males demand greater psychological distance and females insist on greater psychological intimacy. With respect to power, males commonly wish to retain the power and benefits of traditional gender roles while females wish to evolve more egalitarian relationships. Such disagreements may lead to a referral for marital therapy. In well-adjusted couples, partners’ needs for intimacy and power within the relationship are adequately met, and partners have the capacity to negotiate with each other about modifying the relationship if they feel that these needs are being thwarted.

**Types of Marriages**

Fitzpatrick (1988) and Gottman (1993) have both identified three types of stable marriage, in questionnaire and observational studies, respectively. I have termed these ‘traditional’, ‘androgynous’ and ‘avoidant’ couples. Characteristics of these types of marriage are summarised in the first part of Table 1.2. Traditional couples adopt traditional sex roles and lifestyles and take a low key approach to conflict management. Androgynous couples strive to create egalitarian roles and take a fiery approach to conflict resolution. Avoidant couples adopt traditional sex-roles but live parallel lives and avoid conflict. Two types of unstable couples were identified in Gottman’s study. In Table 1.2, I have labelled these conflictual and disengaged couples. The former engage in conflict but without resolution and the latter avoid conflict for much of the time. Gottman found that in all three stable types of couples the ratio of positive to negative verbal exchanges during conflict resolution was 5:1. For both unstable types...
### Table 1.2 Five type of couples

</table>
| Stable    | Traditional couples| They adopt traditional sex roles  
They privilege family goals over individual goals  
They have regular daily schedules  
They share the living space in the family home  
They express moderate levels of both positive and negative emotions  
They tend to avoid conflict about all but major issues  
They engage in conflict and try to resolve it  
At the outset of an episode of conflict resolution, each partner listens to the other and empathises with their position  
In the later part there is considerable persuasion |
| Androgynous couples | They adopt androgynous egalitarian roles  
They privilege individual goals over family goals  
They have chaotic daily schedules  
They have separate living spaces in their homes  
They express high levels of positive and negative emotions  
They tend to engage in continual negotiation about many issues  
Partners disagree and try to persuade one another from the very beginning of episodes of conflict resolution  
They have a high level of both positive and negative emotions |
| Avoidant couples | They adopt traditional sex roles  
They have separate living space in their homes  
They avoid all conflict  
They have few conflict resolution skills  
Partners state their case when a conflict occurs but there is no attempt at persuasion or compromise  
They accept differences about specific conflicts as unimportant compared with their shared common ground and values  
Conflict-related discussions are unemotional |
| Unstable Conflictual couples | They engage in conflict without any constructive attempt to resolve it  
Continual blaming, mind-reading and defensiveness characterise their interactions  
High levels of negative emotion and little positive emotion are expressed  
There is an attack–withdraw interaction pattern |
of couples the ratio of positive to negative exchanges was approximately 1:1. Gottman and Fitzpatrick’s work highlights the fact that there are a number possible models for a stable marital relationship. Their work also underlines the importance of couples engaging in conflict with a view to resolving it rather than avoiding conflict. Negativity is only destructive if it is not balanced out by five times as much positivity. Indeed, negativity may have a prosocial role in balancing the needs for intimacy and autonomy and in keeping attraction alive over long periods.

**Marital Violence**

In the UK, 23% of assaults occur within domestic relationships (British Crime Survey, 2000). In the USA, 12% of couples experience serious marital violence each year (Straus & Gelles, 1990). Marital violence is a multifactorial phenomenon and characteristics of the abuser, the victim, the marital relationship and the wider social context have all been found to contribute to the occurrence and maintenance of the cycle of violence (Frude, 1990; Holtzworth-Munroe, Meehan, Rehman & Marshall, 2002). A personal history of abuse; a high level of the personality trait of aggressiveness; strong conservative attitudes; beliefs in traditional sex roles; low self-esteem; poor social skills; depression; antisocial personality disorder; alcohol abuse; and morbid jealousy have all been found to characterise abusers. Victims, quite understandably have been found to be retaliative and to use verbal and physical abuse during conflict resolution. The majority of couples who seek therapy for domestic violence have engaged in reciprocal violence, but the negative physical and psychological consequences of domestic violence is greater for women than for men. Marriages in which domestic violence occur are typically characterised by a history of multiple separations, a low level of commitment and little marital satisfaction. There is commonly conflict about intimacy, with women demanding more psychological intimacy and men demanding

more physical intimacy. Many rows are about not enough ‘talking and empathy’ from the woman’s perspective and ‘not enough sex’ from the man’s. There is also conflict about power, with the woman having higher status than the man and the man believing in a model of marriage where the male has more power. Many marital disagreements are about money, and this reflects the disagreement about power. Poor communication and negotiation skills characterise these couples, so they cannot resolve their conflicts about intimacy and power. Because they cannot communicate about what they want from each other, they make negative inferences and assumptions about their partners intentions and respond to their partners as if these inferences were accurate. This results in a blaming stance rather than an understanding stance. They also believe that arguments must involve winners and losers and therefore in all conflicts they escalate the exchange so that they can win. They believe in a win–lose model of conflict resolution, not a win–win model. They work on a short-term quid pro quo system, not a long-term goodwill system. This results in attempts to control each other by punishment not reward.

This destructive relational style is more likely to escalate into violence if certain broader contextual factors are present. Violence is more likely where couples live in crowded living conditions; are unemployed; live in poverty; have a low educational level; are socially isolated and have experienced many life changes and stresses recently. With crowding, unemployment and poverty, couples struggle for access to their own limited resources and displace aggression towards societal forces that have trapped them in poverty onto each other. Better educated couples use more sophisticated negotiation skills to prevent conflict escalation. Social isolation increases stress and reduces social support. This stress may lead to heightened arousal and so increase the risk of violence. Also, abusive families may isolate themselves so that the abuse is not uncovered. Major life changes may lead to increased cohesion in some families and increased conflict in others. Moving house, the birth of a baby and redundancy are examples of transitions that may lead to marital violence. Family therapy for couples involved in violence focuses on both risk assessment and helping couples evolve alternatives to violence (Cooper & Vetere, 2005; Holtzworth-Munroe et al., 2002). Multicouple therapy, a recent innovation for the treatment of violent couples, is particularly effective (Stith, McCollum, Rosen, Locke & Goldberg, 2005).

**Families with Children**

In the fifth stage of the family lifecycle model, the main tasks are for couples to adjust their roles as marital partners to make space for young children; for couples’ parents to develop grandparental roles; and for children, as they move into middle childhood, to develop peer relationships.
Parenting Roles

The development of parenting roles involves the couple establishing routines for meeting children’s needs for:

- safety
- care
- control
- intellectual stimulation.

Developing these routines is a complex process. Difficulties in meeting each of these needs may lead to specific types of problems, all of which may become a focus for family therapy (Reder & Lucey, 1995; Reder, McClure & Jolley, 2000; Reder, Duncan & Lucey, 2004). Routines for meeting children’s needs for safety include protecting children from accidents by, for example, not leaving young children unsupervised and also developing skills for managing frustration and anger that the demands of parenting young children often elicit. Failure to develop such routines may lead to accidental injuries or child abuse. Routines for providing children with food and shelter, attachment, empathy, understanding and emotional support need to be developed to meet children’s needs for care in these various areas. Failure to develop such routines may lead to a variety of emotional difficulties. Routines for setting clear rules and limits; for providing supervision to ensure that children conform to these expectations; and for offering appropriate rewards and sanctions for rule following and rule violations meet children’s need for control. Conduct problems may occur if such routines are not developed. Parent–child play and communication routines for meeting children’s needs for age-appropriate intellectual stimulation also need to be developed if the child is to avoid developmental delays in emotional, language and intellectual development.

Attachment

Children who develop secure attachments to their caregivers fare better in life than those who do not (Cassidy & Shaver, 1999). Children develop secure emotional attachments if their parents are attuned to their needs and if their parents are responsive to children’s signals that they require their needs to be met. When this occurs, children learn that their parents are a secure base from which they can explore the world. John Bowlby (1988), who developed attachment theory, argued that attachment behaviour, which is genetically programmed and essential for survival of the species, is elicited in children between six months and three years when faced with danger. In such instances children seek proximity with their caregivers. When comforted they return to the activity of exploring the immediate environment around the caregiver. The cycle repeats each time the child perceives a threat and their attachment needs for satisfaction,
safety and security are activated. Over multiple repetitions, children build internal working models of attachment relationships based on the way these episodes are managed by caregivers in response to children’s needs for proximity, comfort and security. Internal working models are cognitive relationship maps based on early attachment experiences, which serve as a template for the development of later intimate relationships. Internal working models allow people to make predictions about how the self and significant others will behave within relationships. In their ground-breaking text, *Patterns of Attachment*, Mary Ainsworth and colleagues (1978) described three patterns of mother–infant interaction following a brief episode of experimentally contrived separation and further research with mothers and children led to the identification of a fourth category (Cassidy & Shaver, 1999). The four attachment styles are as follows:

1. **Securely attached** children react to their parents as if they were a secure base from which to explore the world. Parents in such relationships are attuned and responsive to the children’s needs. While a secure attachment style is associated with autonomy, the other three attachment styles are associated with a sense of insecurity.

2. **Anxiously attached** children seek contact with their parents following separation but are unable to derive comfort from it. They cling and cry or have tantrums.

3. **Avoidantly attached** children avoid contact with their parents after separation. They sulk.

4. **Children with a disorganised attachment** style following separation show aspects of both the anxious and avoidant patterns. Disorganised attachment is a common correlate of child abuse and neglect and early parental absence, loss or bereavement.

Research on intimate relationships in adulthood confirms that these four relational styles show continuity over the lifecycle (Cassidy & Shaver, 1999). Significant adult relationships and patterns of family organisation may be classified into four equivalent attachment categories, which will be discussed further in Chapter 5, in the section on attachment-based therapies. Difficulties associated with insecure attachment may lead to referrals for marital or family therapy.

**Parenting Styles**

Reviews of the extensive literature on parenting suggest that by combining the two orthogonal dimensions of warmth or acceptance and control, four parenting styles may be identified, and each of these is associated with particular developmental outcomes for the child (Darling & Steinberg, 1993). These four styles are presented in Figure 1.1.
Authoritative parents, who adopt a warm, accepting child-centred approach coupled with a moderate degree of control that allows children to take age-appropriate responsibility, provide a context which is maximally beneficial for children’s development as autonomous confident individuals. Children of parents who use an authoritative style learn that conflicts are most effectively managed by taking the other person’s viewpoint into account within the context of an amicable negotiation. This set of skills is conducive to efficient joint problem-solving and the development of good peer relationships and consequently the development of a good social support network. Children of authoritarian parents, who are warm and accepting but controlling, tend to develop into shy adults who are reluctant to take initiative. The parents’ disciplinary style teaches them that unquestioning obedience is the best way to manage interpersonal differences and to solve problems. Children of permissive parents, who are warm and accepting but lax in discipline, in later life lack the competence to follow through on plans and show poor impulse control. Children who have experienced little warmth or acceptance from their parents and who have been either harshly disciplined or had little or inconsistent supervision develop adjustment problems which may become a focus for family therapy. This is particularly the case with corporal punishment. When children experience corporal punishment, they learn that the use of aggression is an appropriate way to resolve conflicts and tend to use such aggression in managing conflicts with their peers. In this way children who have been physically punished are at risk for developing conduct problems and becoming involved in bullying (Olweus, 1993).

Figure 1.1 Patterns of parenting
Grandparental Roles

In addition to developing parental roles and routines for meeting children’s needs, a further task of the fifth stage of the family lifecycle is the development of grandparental roles and the realignment of family relationships that this entails. Neugarten and Weinstein (1964) identified six types of grandparental roles. First, there were those that adopted a formal role and were not involved in childcare but loving and emotionally involved with the grandchildren. The second role was essentially fun-seeking and these grandparents acted as playmates for the grandchildren. The third type of grandparental role was that of a distant figure who had little contact with grandchildren. The fourth role-type was that of parental surrogate and these grandparents assume the role of parent to the grandchildren so that the mother could work outside the home. The final grandparental role was that of a reservoir of family wisdom who occupied a powerful patriarchal or matriarchal position within the extended family. Where grandparents adopt roles that are supportive of parents and grandchildren, they contribute to family resilience. Where they adopt roles that greatly increase the demands on parents and grandchildren, without offering support, then they may contribute to the development of adjustment problems that become a focus for family therapy.

Children’s Peer Group Roles

Peer group membership is a central part of children’s lives (Dunn, 2004; Kupersmidt & Dodge, 2004; Malik & Furman, 1993). Over the first five years, with increasing opportunities for interaction with others and the development of language, interaction with other children increases. Cooperative play premised on an empathic understanding of other children’s viewpoints gradually emerges and is usually fully established by middle childhood. Competitive rivalry (often involving physical or verbal aggression or joking) is an important part of peer interactions, particularly among boys. This allows youngsters to establish their position of dominance within the peer group hierarchy. There are important sex differences in styles of play adopted, with girls being more cooperative and relationship-focused, and boys being more competitive and activity-focused. Boys tend to play in larger peer groups whereas girls tend to play within small groups characterised by emotionally intimate exclusive friendships. Sex segregated play is almost universal in middle childhood.

Peer friendships are important because they constitute an important source of social support and a context within which to learn about the management of networks of relationships. Children who are unable to make and maintain friendships, particularly during middle childhood and early adolescence, are at risk for the development of psychological difficulties. Children who have developed secure attachments to their
parents are more likely to develop good peer friendships. This is probably because their experience with their parents provides them with a useful cognitive model on which to base their interactions with their peers. Children reared in institutions have particular difficulty with peer relationships in their teens.

Popular children are described by their peers as helpful, friendly, considerate and capable of following rules in games and imaginative play. They also tend to be more intelligent and physically attractive than average. They accurately interpret social situations and have the social skills necessary for engaging in peer group activities. About 10–15% of children are rejected by their peer-group. In middle childhood two main types of unpopular child may be distinguished: the aggressive youngster and the victim. Victims tend to be sensitive, anxious, have low self-esteem and lack the skills required to defend themselves and establish dominance within the peer-group hierarchy. They are often the targets for bullies (Olweus, 1993). Unpopular aggressive children are described by peers as disruptive, hyperactive, impulsive and unable to follow rules in games and play. Their aggression tends to be used less for establishing dominance or a hierarchical position in the peer group and more for achieving certain instrumental goals. For example, taking a toy from another child.

Popular children are effective in joining in peer group activities. They hover on the edge, tune-in to the groups activities and carefully select a time to become integrated into the group’s activities. Unpopular children, particularly the aggressive type, do not tune-in to group activities. They tend to criticize other children and talk about themselves rather than listening to others. Warmth, a sense of humour and sensitivity to social cues are important features of socially skilled children. Unpopular children, particularly the aggressive type, are predisposed to interpreting ambiguous social cues negatively and becoming involved in escalating spirals of negative social interaction.

Unpopularity is relatively stable over time. A child who is unpopular this year is likely to remain so next year and this unpopularity is not wholly based on reputation. For the aggressive unpopular child, inadequate cognitive models for relationships, difficulties in interpreting ambiguous social situations and poor social skills appear to be the main factors underpinning this stability of unpopularity. For the unpopular victim the continued unpopularity is probably mediated by low self-esteem, avoidance of opportunities for social interaction and a lack of pro-social skills. Also, both types of unpopular children miss out on important opportunities for learning about cooperation, teamwork and the management of networks of friendships. While unpopularity is not uniformly associated with long-term difficulties, it appears to put such youngsters at risk for developing academic problems, dropping out of school, conduct problems in adolescence, mental health
problems in adulthood and criminality. Multisystemic family therapy (described in Chapter 5), which includes school-based consultations and social skills training, is a useful approach when working with unpopular children.

**Families with Adolescents**

In the sixth stage of the family lifecycle model, which is marked by children’s entry into adolescence, parent–child relationships require realignment to allow adolescents to develop more autonomy. Concurrently, demands of caring for ageing grandparents may occur. This is an extremely complex and demanding stage of the family lifecycle, particularly for parents.

*Facilitating the Growth of Adolescent Autonomy*

Good parent–child communication and joint problem-solving skills facilitate the renegotiation of parent–child relationships and the growth of adolescent autonomy. Skills deficits in these areas may underpin referrals for family therapy. Results of empirical studies of adolescent relationships with parents, peers and partners contradict many commonly held misconceptions (Coleman & Hendry, 1999; Rice & Dolgin, 2004). Psychoanalytic writers, on the basis of clinical observations of distressed adolescents, argued that parent–child conflict is the norm in adolescence. Epidemiological studies of adolescents show that this is not the case. While one in five families experience some parent–child conflict, only one in 20 experience extreme conflict. A traditional view of adolescence is one where a visionary adolescent confronts conservative parental values. Epidemiological studies show that in most families parent–adolescent quarrels are about mundane topics such as untidiness, music, clothing and curfew-time. They are rarely about values or ethics. A traditional view of adolescence posits a gradual erosion of the quality of parent–adolescent relationships with a complementary increase in the quality of the adolescent–peer relationships. Studies of attachment suggest that this is not the case. Secure attachments to parents are correlated with secure attachments to peers.

Promiscuity in adolescence is not the norm. Most surveys show that a majority of older teenagers view premarital sex between committed partners as acceptable. Premarital sex with multiple partners is viewed as unacceptable. Teenage pregnancy is a risk factor for later adjustment primarily because it may interfere with education and compromise the career prospects of the teenager. Adolescent marriages resulting from unplanned pregnancies run a high risk of dissolution, and these young families often develop multiple life problems and require particularly intensive multisystemic intervention.
Resilience in Adolescence

Adolescence is a risky period (Coleman & Hendry, 1999; Rice & Dolgin, 2004). Opportunities for developing a wide variety of psychological problems abound. A central concern for many parents and practitioners is knowing the degree to which the dice is loaded in favour of the adolescent emerging from adolescence relatively unscathed. Factors that characterise adolescents and children who are resilient in the face of adversity are summarised in Table 1.3 (Carr, 2004; Luthar, 2003). Adolescents are more likely to show good adjustment if they have an easy temperament and a high level of intellectual ability. A high level of self-esteem, a general belief in control over one’s life and a specific belief that factors related to specific stresses may be controlled are all associated with good adjustment. Adolescents will be less adversely affected by life stresses if they have good planning skills, if they can elicit social support from family and peers, if they have a sense of humour and if they can empathise with others. Better adjustment to life stress occurs when adolescents come from higher socioeconomic-groups, have good social support networks comprising family members and peers, and attend schools that provide a supportive yet challenging educational environment. Secure attachment relationships to primary caregivers, the use of an authoritative parenting style and the involvement of both mothers and fathers in parenting are the

major positive family factors associated with adolescents’ adjustment to life stress. The absence of childhood separations, losses, bereavements, parental mental health problems, criminality and marital discord also characterise the families of children who are resilient in the face of stress.

**Grandparental Care**

Increasingly, with the lengthening of the average lifespan, the responsibility of caring for ageing parents is becoming a routine responsibility for men and women in midlife. The stress associated with this role and the impending death of the ageing parent tends to be most acutely felt by daughters of ageing parents. Social support from family and friends and periodic relief custodial care are important coping resources for such daughters to employ in managing the stresses of caring for ageing parents. Family therapists have a role to play in helping families manage this important task of sharing the stresses associated with caring for ageing family members (Richardson, Gillear, Lieberman & Peeler, 1994).

**Launching**

The seventh stage of the family lifecycle model is concerned with the transition of young adult children out of the parental home. Ideally this transition entails the development of a less hierarchical relationship between parents and children. During this stage, the parents are faced with the task of adjusting to living as a couple again, to dealing with disabilities and death in their families of origin and of adjusting to the expansion of the family if their children marry and procreate. However, the process of midlife re-evaluation, which began in the previous life-cycle stage, takes on a particular prominence as the nest empties.

**Midlife Re-evaluation**

As adolescents grow up and begin to leave home parents must contend not only with changes in their relationships with their maturing children but also with a midlife re-evaluation of their marital relationship and career aspirations. Just as the notion of the universality of adolescent rebellion has not been supported by the results of carefully conducted community-based surveys, so also the popular conception of the midlife crisis has been found to be a relatively rare phenomenon (Papalia, Wendkos-Olds, Duskin & Feldman, 2001; Santrock, 2003). Longitudinal studies show that many men and women in their 40s become more introspective and re-evaluate their roles within the family and the world of work. For men,
there may be a shift in values with an increased valuing of family life over work life. For women, there may be an increased emphasis on work over family. However, these changes in values rarely lead to changes that assume crisis proportions.

Gould (1981) has shown in an extensive study of clinical and non-clinical populations that the assumptions and belief systems learned within the family of origin are challenged in a gradual way over the course of adulthood, and this process reaches a resolution in midlife. Gould’s findings are summarised in Table 1.4. The assumptions of childhood give a sense of safety and security. They include a belief in omnipotent thought; a belief in omnipotent protective parents; a belief in the absoluteness of the parents’ world view; and defences against a rage reaction to separation.

</tbody>
</table>

Adult consciousness on the other hand is governed by an acceptance that we create our own lives according to beliefs and values that are different from those internalised in childhood.

In the late teens, if the adolescent is to be liberated from the family, the parents’ world view must be appraised. The parents’ roles as protectors must be evaluated and their command over the youth’s sexuality and body must be challenged. The conflict is between retaining a childhood role and trying out new roles.

In the 20s, within the work arena, the idea that life is fair and if you stick to the rules you will win, is challenged. With relationships, the idea that our partners can make up for our deficiencies and we can make up for theirs is also challenged at this time. The idea that love can cure personal deficiencies must be given up during the 20s. For example, a talkative partner can’t make up for a quiet partner’s style nor can a nurturant partner fulfil all their partner’s dependency needs. When these assumptions have been challenged, the person is in a position to differentiate sufficiently to establish a family separate from the family of origin.

The assumptions that are challenged up to the 20s relate to the outer world. In the 30s, assumptions about our inner selves or our relationships with ourselves are challenged. The person realises that one can know something intellectually such as ‘this row with my partner can be resolved through patient negotiation’, and yet lack the emotional knowledge to work through the process of negotiation. In the 30s people realise that they have many characteristics of their parents, which they dislike. For example, they may treat their children unfairly. This has to be recognised if patterns are not to be repeated across generations. There must be an acceptance of a partner’s evolution and growth, and the fact that we cannot assume that we see their point of view today just because we saw it a year ago. There are many threats to security in midlife both within marriage and the workplace. Perceived threats within marriage are often projections, rather than realistic threats.

People in their 30s assume that the feelings of being mistreated or taken for granted are real threats from their partners rather than projections onto their partners of ways in which they were treated as children by their parents or significant others. The belief that we can always identify and deal with threats accurately must be challenged in midlife.

In the 40s illusions of safety are challenged. For men, the most common illusion is ‘If I am successful I will never be frightened again’. For women, the most widespread illusion is ‘I cannot be safe without a man to protect me’. When these illusions are challenged, both men and women are freed from slavish adherence to career or marital roles to make the best use of their remaining years with an awareness of their mortality in mind. Within marriage, both husbands and wives must challenge the belief that there is no life outside the marriage. This may lead to them choosing to separate or choosing consciously to live together. The choice to remain married enriches the marriage. In midlife there must be a reappraisal of
the idea that we are innocent, since this is usually a defence against the childhood tendency to label certain emotional states as bad or unacceptable. There is an examination of how we label these emotional experiences rather than a continued attempt to try to deny them. For example:

- anger need not be labelled destructiveness
- pleasure need not be labelled as irresponsibility
- sensuality need not be labelled as sinfulness
- wicked thoughts need not entail wicked actions
- dissatisfaction need not be labelled as greed
- love need not be labelled as weakness
- self-concern need not be labelled as selfishness.

When these aspects of the self are relabelled rather than denied and integrated into the conscious self a process of liberation and increased psychological vitality occurs. For Gould (1981), at the end of the midlife period the adult experiences a consciousness where the guiding belief is ‘I own myself’ rather than ‘I am theirs’. The sense of self-ownership gives life meaning.

Couples who seek marital and family therapy in midlife are often preoccupied with the consolidation of an adult consciousness, as described by Gould.

**Later Life, Illness and Death**

In the final stage of the family lifecycle model, the family must cope with the parents’ physiological decline, and approaching death, while at the same time developing routines for benefiting from the wisdom and experience of the elderly. A central issue for all family members in this stage as parents move into later life is coping with their approaching death, possible terminal illness and the inevitability of death and ultimately bereavement. Following bereavement or during adjustment to life-threatening illness, families may be referred for therapy because one or more of their members display adjustment difficulties, such as those listed in Table 1.5. All of these types of problems typically reflect involvement in the following grief processes:

- shock
- denial or disbelief
- yearning and searching
- sadness
- anger
- anxiety
- guilt and bargaining
- acceptance.

</tbody>
</table>
There is not a clear-cut progression through these processes from one to the next (Stroebe, Hansson, Stroebe & Schut, 2001; Walsh & McGoldrick, 2004). Rather, at different points in time, one or other process predominates when a family member has experienced a loss or faces death. There may also be movement back and forth between processes.

**Shock and Denial**

Shock is the most common initial reaction, it can take the form of physical pain, numbness, apathy or withdrawal. The person may appear to be stunned and unable to think clearly. This may be accompanied by denial, disbelief or avoidance of the reality of the bereavement, a process can last minutes, days, even months. During denial people may behave as if the dead family member is still living, albeit elsewhere. Thus, the bereaved may speak about future plans that involve the deceased. Terminally ill people may talk about themselves and their future as if they were going to live indefinitely.

**Yearning and Searching**

A yearning to be with the deceased, coupled with disbelief about their death, may lead younger family members to engage in frantic searches for the dead person, wandering or running away from the home in a quest for the person who has died. Children or grandchildren within the family may phone relatives or friends trying to trace the person who has died. During this process, those who have lost family members may report seeing them or being visited by them. Some children carry on full conversations with what presumably are hallucinations of the deceased person. Mistaking other people for the deceased is also a common experience during the denial process. With terminal illness, the yearning for health may lead to a frantic search for a miracle cure and to involvement in alternative medicine.

**Sadness**

When denial gives way to a realisation of the reality of death, family members may experience profound sadness, despair, hopelessness and depression. The experience of sadness may be accompanied by low energy, sleep disruption, a disturbance of appetite, tearfulness, an inability to concentrate and a retreat from social interaction. Young children or grandchildren experiencing the despair process may regress and begin to behave as if they were a baby again wetting their beds and sucking their thumbs, hoping that by becoming a baby, the dead person may return to comfort them. With terminal illness, despair, hopelessness and depression finds expression in an unwillingness to fight the illness.
Anger

Complementing the despair process, there is an anger process associated with the sense of having been abandoned. Aggression, conflict within the family and the wider social system, and drug and alcohol abuse are some of the common ways that grief-related anger finds expression. With terminal illness, the anger may be projected onto family members or members of the medical team. Destructive conflicts within these relationships may occur, such as refusal to adhere to medical regimes, to take medication or to participate in physiotherapy.

Anxiety

The expression of such anger, may often be followed by remorse or fear of retribution. Young children or grandchildren may fear that the deceased family member will punish them for their anger and so it is not surprising that they may want to leave the light on at night and may be afraid to go to bed alone. In adolescents and adults anxiety is attached to reality-based threats. So, where a family member has been lost through illness or accident, those grieving may worry that they too will die from similar causes. This can lead to a belief that one is seriously ill and to a variety of somatic complaints, such as stomach aches and headaches. It may also lead to a refusal to leave home, lest a fatal accident occur. Referral for assessment of separation anxiety, recurrent abdominal pain, headaches, hypochondriasis and agoraphobia may occur in these cases.

Guilt and Bargaining

The guilt process is marked by self-blame for causing or not preventing the death of the deceased. Family members may also find themselves thinking that if they died this might magically bring back the deceased. Thus, the guilt process may underpin suicidal ideation or self-injury, which invariably leads to referral for mental health assessment. With terminal illness, the illness may be experienced as a punishment for having done something wrong. This sense of guilt underpins the bargaining process in which people facing death engage. The bargaining process may be carried out as imagined conversations with a deity, where the dying person makes promises to live a better life if they are permitted to live longer.

Acceptance

The final grief process is acceptance. With bereavement, the surviving family members reconstruct their view of the world so that the deceased person is construed as no longer living in this world, but a benign and accessible representation of them is constructed that is consistent with the family’s belief system. For example, a Christian may imagine that the deceased is in heaven. Atheists may experience the deceased as living on
in their memory or in projects or photographs left behind. In terminal illness, acceptance involves a modification of the worldview so that the future is foreshortened and therefore the time remaining is highly valued and is spent living life to the full rather than searching in vain for a miracle cure. For bereaved families, new lifestyle routines are evolved as part of the process of accepting the death of a family member and the family is reorganised to take account of the absence of the deceased person. With terminal illness, once the family accept the inevitability of imminent death, routines that enhance the quality of life of the dying person may be evolved. A summary of the grief processes and related adjustment problems that may lead to referral is presented in Table 1.5.

Variability in Grief Responses

Reviews of empirical studies of bereavement confirm that there is extraordinary variation in grief processes and the following points have been well substantiated (Kissane & Bloch, 2002; Shackleton, 1983; Stroebe et al., 2001; Walsh & McGoldrick, 2004; Wortman & Silver, 1989). First, not everyone needs to work through their sense of loss by immediate intensive conversation about it. Second, depression following bereavement is not universal. Only about a third of people suffer depression following bereavement. Third, failure to show emotional distress initially does not necessarily mean that later adjustment problems are inevitable. It appears that different people use different coping strategies to cope with loss. Some use distraction or avoidance, while others use confrontation of the grief experience and working through. Those that effectively use the former coping strategy may not show emotional distress. Fourth, extreme distress following bereavement commonly occurs in those who show protracted grief reactions. Fifth, many people who work through their sense of loss early have later problems. Sixth, a return to normal functioning does not always occur rapidly. While the majority of people approximate normal functioning within two years, a substantial minority of bereaved people continue to show adjustment difficulties even seven years after bereavement. Seventh, resolution and acceptance of death does not always occur. For example, parents who lose children or those who lose a loved one in an untimely fatal accident show protracted patterns of grief. Eighth, grief may have a marked effect on physical functioning. Infections and other illnesses are more common among bereaved people and this is probably due to the effect of loss-related stress on the functioning of the immune system. However, with the passage of time immune-system functioning returns to normal. Ninth, children’s grief reactions tend to be similar in form to those of adults but to be briefer and less intense, probably because in comparison with adults, children do not tend to focus for a protracted time period on memories or lost possibilities concerning the bereaved person. Tenth, the quality of family relationships may change in response to bereavement or terminal
illness, with discordant relationships becoming more discordant and supportive relationships remaining so. Finally, bereavement, particularly loss of a parent, leaves young children vulnerable to depression in adult life. Adults bereaved as children have double the risk of developing depression when faced with a loss experience in adult life compared with their non-bereaved counterparts. Bereaved children most at risk for depression in adulthood are girls who were young when their parents died a violent or sudden death, and who subsequently received inadequate care associated with the surviving parent experiencing a prolonged grief reaction.

Having considered a family lifecycle model that assumes lifelong monogamy, lifecycle models that address other types of family arrangements deserve attention, particularly those that evolve when separation, divorce and remarriage occurs.

**LIFECYCLE STAGES ASSOCIATED WITH SEPARATION AND DIVORCE**

Divorce is no longer considered to be an aberration in the normal family lifecycle, but a normative transition for a substantial minority of families (Greene, Anderson, Hetherington, Forgatch & DeGarmo, 2003; Haskey, 1999). In the USA and the UK, between a third and a half of marriages end in divorce. Family transformation through separation, divorce and remarriage may be conceptualised as process involving a series of stages. Carter and McGoldrick’s (1999) model of the stages of adjustment to divorce is presented in Table 1.6. This model outlines tasks that must be completed during various stages of the transformation process that involves separation and remarriage. Failure to complete tasks at one stage, may lead to adjustment problems for family members at later stages and referrals for couples or family therapy (Emery & Sbarra, 2002).

**Decision to Divorce**

In the first stage, the decision to divorce occurs and accepting one’s own part in marital failure is the central task. However, it is useful to keep in mind that many contextual factors contribute to divorce including socioeconomic status (SES), urban/rural geographical location, age at marriage, premarital pregnancy, psychological adjustment and parental divorce (Faust & McKibben, 1999; Raschke, 1987). Divorce is more common among those from lower socioeconomic groups with psychological problems who live in urban areas and who have married before the age of 20. It is also common where premarital pregnancy has occurred and where parental divorce has occurred. Divorce is less common among those from higher socioeconomic groupings without psychological problems who live in rural areas and who have married after the age of 30. Where
premarital pregnancy has not occurred and where the couples’ parents are still in their first marriage divorce is also less common. The economic resources associated with high SES, the community integration associated with rural living, the psychological resources associated with maturity and the model of marital stability offered by non-divorced parents are

</table>

the more common explanations given for the associations among these factors associated with divorce. The relationship between these various factors and divorce while consistent, are moderate to weak. That is, there are significant subgroups of people who show some or all of these risk factors but do not divorce.

**Separation**

In the second stage of the lifecycle model of divorce, plans for separation are made. A cooperative plan for custody of the children, visitation, finances and dealing with families of origin’s response to the plan to separate must be made if positive adjustment is to occur. Mediation may facilitate this process (Folberg, Milne & Salem, 2004). The third stage of the model is separation. Mourning the loss of the intact family; adjusting to the change in parent–child and parent–parent relationships; preventing marital arguments from interfering with interparental cooperation, staying connected to the extended family and managing doubts about separation are the principal tasks at this stage.

Divorce leads to multiple life changes that affect parental well-being, and the impact of these changes on parental well-being is mediated by a range of personal and contextual factors (Amato, 2000; Anderson, 2003; Hetherington & Kelly, 2002). Divorce leads custodial parents to experience major changes in their lives, including a change in residential arrangements, economic disadvantage, loneliness associated with social network changes, and role-strain associated with the task overload that results from having to care for children and work outside the home. Non-custodial parents experience all of these changes with the exception of role-strain. Changes in divorced couples’ residential arrangements, economic status, social networks and role demands lead to a deterioration in physical and mental health for the majority of individuals immediately following separation. Mood swings, depression, identity problems, vulnerability to common infections, and exacerbation of previous health problems are all common sequelae for adults who have separated or divorced. However, for most people these health problems abate within two years of the separation.

**Post-divorce Period**

The fourth stage of the lifecycle model of divorce is the post-divorce period. Here couples must maintain flexible arrangements about custody, access and finances without detouring conflict through the children; retain strong relationships with the children; and re-establish peer relationships. The stresses and strains of residential changes, economic hardship, role changes and consequent physical and psychological difficulties
associated with the immediate aftermath of separation may compromise parents’ capacity to cooperate in meeting their children’s needs for safety, care, control, education and relationships with each parent (Amato, 1993, 2000, 2001; Amato & Gilbreth, 1999). Authoritarian–punitive parenting, lax laissez-faire or neglectful parenting, and chaotic parenting, which involves oscillating between both of these extreme styles, are not uncommon among both custodial and non-custodial parents who have divorced. Couples vary in the ways in which they coordinate their efforts to parent their children following divorce. Three distinct coparenting styles have been identified in studies of divorced families (Bray & Hetherington, 1993). With cooperative parenting, a unified and integrated set of rules and routines about managing the children in both the custodial and non-custodial households is developed. This is the optimal arrangement but only occurs in about one in five cases. With parallel parenting, each parent has his or her own set of rules for the children and no attempt is made to integrate these. Most children show few adjustment problems when parallel parenting occurs and this is the most common pattern. When conflictual parenting occurs, the couple do not communicate directly with each other. All messages are passed through the child and this go-between role, forced on the child, is highly stressful and entails sustained adjustment problems.

Parental separation and divorce are major life stressors for all family members. For children, the experiences of separation and divorce may lead to short- and longer-term adjustment reactions (Amato, 2000, 2001; Amato & Gilbreth, 1999; Hetherington & Kelly, 2002; Kelly, 2000; Leon, 2003; Reifman, Villa, Amans, Rethinam & Telesca, 2001; Rogers, 2004; Wallerstein, 1991). During the two-year period immediately following divorce, most children show some adjustment problems. Boys tend to display conduct or externalising behaviour problems and girls tend to experience emotional or internalising behaviour problems. Both boys and girls may experience educational problems and relationship difficulties within the family, school and peer group. The mean level of maladjustment has consistently been found to be worse for children of divorce in comparison with those from intact families on a variety of measures of adjustment, including conduct difficulties, emotional problems, academic performance, self-esteem and relationships with parents. This has led to the erroneous conclusion by some interpreters of the literature that divorce always has a negative effect on children. When the impact of divorce on children is expressed in terms of the percentages of maladjusted children, it is clear that divorce leads to maladjustment for only a minority of youngsters. A small proportion of individuals from families where divorce has occurred have difficulty making and maintaining stable marital relationships, have psychological adjustment difficulties and attain a lower socioeconomic level in comparison with adults who have grown up in intact families.

Certain characteristics of children and certain features of their social contexts mediate the effects of parental divorce on their adjustment
GOALS OF FAMILY THERAPY ACROSS THE LIFECYCLE 33

(Amato, 2000, 2001; Amato & Gilbreth, 1999; Anderson, 2003; Faust & McKibben, 1999; Hetherington & Kelly, 2002; Greene et al., 2003; Kelly, 2000; Leon, 2003; Reifman et al., 2001; Rogers, 2004; Visher, Visher & Pasley, 2003; Wallerstein, 1991). In terms of personal characteristics, males between the ages of three and 18 years are particularly at risk for post-divorce adjustment problems, especially if they have biological or psychological vulnerabilities. Biological vulnerabilities may result from genetic factors, prenatal and perinatal difficulties, or a history of serious illness or injury. Psychological vulnerabilities may be entailed by low intelligence, a difficult temperament, low self-esteem, an external locus of control, or a history of previous psychological adjustment problems. Specific features of children's families and social networks may render them vulnerable to adjustment difficulties following parental separation or divorce. Children are more likely to develop post-separation difficulties if there have been serious difficulties with the parent–child relationship prior to the separation. Included here are insecure attachment, inconsistent discipline and authoritarian, permissive or neglectful parenting. Exposure to chronic family problems including parental adjustment problems, marital discord, domestic violence, family disorganisation, and a history of previous separations and reunions also place children at risk for post-separation adjustment problems. Early life stresses, such as abuse or bereavement, may also compromise children's capacity to deal with stresses entailed by parental separation. In contrast to these factors that predispose children to post-separation adjustment difficulties, better post-separation adjustment occurs where youngsters have a history of good physical and psychological adjustment and where their families have offered a stable parenting environment.

Following parental separation, adjustment difficulties may be maintained by a variety of psychological factors within the child and a range of psychosocial factors within the child's family and social network (Amato, 2000, 2001; Amato & Gilbreth, 1999; Anderson, 2003; Faust & McKibben, 1999; Hetherington & Kelly, 2002; Greene et al., 2003; Kelly, 2000; Leon, 2003; Reifman et al., 2001; Rogers, 2004; Visher et al., 2003; Wallerstein, 1991). At a personal level, adjustment problems may be maintained by rigid sets of negative beliefs related to parental separation. These beliefs may include the view that the child caused the separation and has the power to influence parental reunification, or a belief that abandonment by parents and rejection by peers is inevitable. Within the child’s family and social network, adjustment problems following separation may be maintained by sustained parental conflict and routine involvement of the child in this ongoing parental acrimony. The use of non-optimal parenting styles, a lack of consistency in parental rules and routines across custodial and non-custodial households, a lack of clarity about new family roles and routines within each household, and confused family communication may all maintain children’s post-separation adjustment
problems. These parenting and coparenting problems that maintain children’s adjustment difficulties are in turn often a spin-off from parents’ personal post-separation adjustment problems. The degree to which parental post-separation problems compromise their capacity to provide a coparenting environment that minimises rather than maintains their children’s adjustment reactions is partially determined by the stresses that parents face in the aftermath of separation. These include the loss of support, financial hardship and social disadvantage.

In contrast to these factors that maintain post-separation adjustment difficulties, better post-separation adjustment occurs in youngsters who have psychological strengths, such as high self-esteem, an internal locus of control, realistic beliefs about their parents separation and divorce, good problem-solving skills and good social skills. In terms of the child’s family and social network, better adjustment occurs usually after a two-year period has elapsed, where parental conflict is minimal and not channelled through the child, and where an authoritative parenting style is employed. Where parents cope well with post-separation grief, have good personal psychological resources, and a high level of satisfaction within their new relationships, children show better post-separation adjustment. Parental commitment to resolving child-management difficulties and a track record of coping well with transitions in family life may be viewed as protective factors. The availability of social support for both parents and children from the extended family and peers and the absence of financial hardship are also protective factors for post-separation adjustment. Where the school provides a concerned student-centred, achievement-oriented ethos with a high level of student contact and supervision, children are more likely to show positive adjustment following separation. The factors discussed above have a cumulative effect, with more predisposing and maintaining factors being associated with worse adjustment and more protective factors being associated with better adjustment.

New Relationships

Establishing a new relationship occurs in the fifth stage of the divorce lifecycle model. For this to occur, emotional divorce from the previous relationship must be completed and a commitment to a new marriage must be developed. The sixth stage of the model is planning a new marriage. This entails planning for cooperative coparental relationships with ex-spouses and planning to deal with children’s loyalty conflicts involving natural and step-parents. It is also important to adjust to the widening of the extended family. In the final stage of the model establishing a new family is the central theme. Realigning relationships within the family to allow space for new members and sharing memories and histories to allow for integration of all new members are the principal tasks of this stage.
Step-families have unique characteristics that are, in part, affected by the conditions under which they are formed (Hetherington & Kelly 2002; Raschke, 1987; Visher et al., 2003). On the positive side, surveys of step-families have found them to be more open in communication, more willing to deal with conflict, more pragmatic, less romantic and more egalitarian with respect to childcare and housekeeping tasks. On the negative side, compared with intact first marriages, step-families are less cohesive and more stressful. Step-parent–child relationships on average tend to be more conflictual than parent–child relationships in intact families. This is particularly true of step-father–daughter relationships and may be due to the daughter’s perception of the step-father encroaching on a close mother–daughter relationship.

Children’s adjustment following remarriage is associated with age, gender and parents’ satisfaction with the new marriage (Greene et al., 2003; Hetherington & Kelly, 2002; Visher et al., 2003). Good adjustment occurs when the custodial parent remares while children are pre-adolescent, in their late adolescence or in early adulthood. All children in divorced families resist the entry of a step-parent. But during the early teenage years (10–15) this resistance is at a maximum. Divorced adults with children in middle childhood and early adolescence who wish to remarry should try to wait until after the children have reached about 16–18 years, if they want their new relationship to have a fair chance of survival. Remarriage is more disruptive for girls than for boys. Marital satisfaction in the new relationship has a protective effect for young boys and it is a risk factor for preadolescent girls. Young boys, benefit from their custodial mothers forming a satisfying relationship with a new partner. Such satisfying relationships lead step-fathers to behave in a warm, child-centred way towards their step-sons and to help them learn sports and academic skills. These skills help young boys become psychologically robust. Preadolescent girls feel that the close supportive relationship they have with their divorced mothers is threatened by the development of a new and satisfying marital relationship. They usually respond with increased conduct problems and psychological difficulties. In adolescence, when the remarriage has occurred while the children were pre-adolescent, a high level of marital satisfaction is associated with good adjustment and a high level of acceptance of the step-parent for both boys and girls.

Adjustment problems arising from difficulties with managing the developmental tasks associated with family transformation through separation, divorce and remarriage may lead to a referral for family therapy.

**THE INDIVIDUAL LIFECYCLE**

In practising family therapy, the lifecycle of the family offers one important developmental framework within which to conceptualise problems.
However, it is also useful for therapists to conceptualise the dilemmas faced by each individual at various lifecycle stages. For this reason, a cursory review of a model of the individual lifecycle follows. Newman and Newman’s (2003) modification of Erik Erikson’s (1959) model of identity development is presented in Table 1.7. The model has been selected because it pinpoints personal dilemmas that must be resolved at various stages of development, which have particular relevance for participating in family life. In this model it is assumed that at each stage of social development the individual must face a personal dilemma. The ease with which successive dilemmas are managed is determined partly by the success with which preceding dilemmas were resolved and partly by the quality of relationships within the individual’s family and social context.

**Trust vs Mistrust**

The main psychosocial dilemma to be resolved during the first two years of life is trust versus mistrust. If parents are responsive to infants’ needs in a predictable and sensitive way, the infant develops a sense of trust. In the long term, this underpins a capacity to have hope in the face of adversity and to trust, as adults, that difficult challenges can be resolved. If the child does not experience the parent as a secure base from which to explore the world, the child learns to mistrust others and this underpins a view of the world as threatening. This may lead the child to adopt a detached position during later years and difficulties with making and maintaining peer relationships may occur (Cassidy & Shaver, 1999).

**Autonomy vs Shame and Doubt**

The main psychosocial dilemma in the pre-school years is autonomy versus shame and doubt. During this period children become aware of their separateness and strive to establish a sense of personal agency and impose their will on the world. Of course, sometimes this is possible, but other times their parents will prohibit them from doing certain things. There is a gradual moving from the battles of the ‘terrible twos’ to the ritual orderliness that many children show as they approach school-going age. Routines develop for going to bed or getting up, mealtimes and playtimes. The phrase ‘I can do it myself’ for tying shoelaces or doing their buttons are examples of the appropriate channelling of the desire to be autonomous. If parents patiently provide the framework for children to master tasks and routines, autonomy develops together with a sense of self-esteem (Darling & Steinberg, 1993). As adults, such children are patient with themselves and have confidence in their abilities to master the challenges of life. They have high self-esteem and a strong sense of will and self-efficacy. If parents are unable to be patient with the child’s

*Stages marked with * are Newman’s additions to Erikson’s original model.
evolving wilfulness and need for mastery and criticise or humiliate failed attempts at mastery, the child will develop a sense of self-doubt and shame. The lack of patience and parental criticism will become internalised and children will evolve into adults who criticise themselves excessively and who lack confidence in their abilities. In some instances this may lead to the compulsive need to repeat their efforts at problem solving so that they can undo the mess they have made and so cope with the shame of not succeeding.

**Initiative vs Guilt**

At the beginning of school-going years the main psychosocial dilemma is initiative versus guilt. When children have developed a sense of autonomy in the preschool years, they turn their attention outwards to the physical and social world and use their initiative to investigate and explore its regularities with a view to establishing a cognitive map of it. The child finds out what is allowed and what is not allowed at home and at school. Many questions about how the world works are asked. Children conduct various experiments and investigations, for example by lighting matches, taking toys apart, or playing doctors and nurses. The initiative versus guilt dilemma is resolved when the child learns how to channel the need for investigation into socially appropriate courses of action. This occurs when parents empathise with the child’s curiosity but establish the limits of experimentation clearly and with warmth (Darling & Steinberg, 1993). Children who resolve the dilemma of initiative versus guilt, act with a sense of purpose and vision as adults. Where parents have difficulty empathising with the child’s need for curiosity and curtail experimentation unduly, children may develop a reluctance to explore untried options as adults because such curiosity arouses a sense of guilt.

**Industry vs Inferiority**

At the close of middle childhood and during the transition to adolescence, the main psychosocial dilemma is industry versus inferiority. Having established a sense of trust, of autonomy and of initiative, the child’s need to develop skills and engage in meaningful work emerges. The motivation for industry may stem from the fact that learning new skills is intrinsically rewarding and many tasks and jobs open to the child may be rewarded. Children who have the aptitude to master skills that are rewarded by parents, teachers and peers emerge from this stage of development with new skills and a sense of competence and self-efficacy about these.

Unfortunately, not all children have the aptitude for skills that are valued by society. Youngsters who have low aptitudes for literacy skills, sports and social conformity are disadvantaged from the start. This is
compounded by the fact that in our culture, social comparisons are readily made through, for example, streaming in schools and sports. In our society, failure is ridiculed. Youngsters who fail and are ridiculed or humiliated develop a sense of inferiority and in adulthood lack the motivation to achieve (McEvoy & Walker, 2000).

**Group Identity vs Alienation**

The young adolescent faces a dilemma of group identity versus alienation. There is a requirement to find a peer group with which to become affiliated so that the need for belonging will be met. Joining such a group, however, must not lead to sacrificing one’s individuality and personal goals and aspirations. If young adolescents are not accepted by a peer group they will experience alienation. In the longer term they may find themselves unaffiliated and have difficulty developing social support networks, which are particularly important for health and well-being. To achieve group identity, their parents and school need to avoid overrestriction of opportunities for making and maintaining peer relationships. This has to be balanced against the dangers of overpermissiveness since lack of supervision is associated with conduct problems and drug dependence (Burke, Loeber & Birmaher, 2002; Crome, Ghodse, Gilvarry & McArdle, 2004; Loeber, Burke, Lahey, Winters & Zera, 2000).

**Identity vs Role Confusion**

While the concern of early adolescence is group membership and affiliation, the establishment of a clear sense of identity – that is, a sense of who I am – is the major concern in late adolescence. Marcia (1981) has found that adolescents may achieve one of four identity states. With identity diffusion there is no firm commitment to personal, social, political or vocational beliefs or plans. Such individuals are either fun-seekers or people with adjustment difficulties and low self-esteem. With foreclosure, vocational, political or religious decisions are made for the adolescent by parents or elders in the community and are accepted without a prolonged decision-making process. These adolescents tend to adhere to authoritarian values. In cases where a moratorium is reached, the adolescent experiments with a number of roles before settling on an identity. Some of these roles may be negative (delinquent) or non-conventional (drop-out/commune dweller). However, they are staging posts in a prolonged decision-making process on the way to a stable identity. Where adolescents achieve a clear identity following a successful moratorium, they develop a strong commitment to vocational, social, political and religious values, and usually have good psychosocial adjustment in adulthood. They have high self-esteem, realistic goals, a stronger sense of independence and are more
resilient in the face of stress. Where a sense of identity is achieved following a moratorium in which many roles have been explored, the adolescent avoids the problems of being aimless, as in the case of identity diffusion, or trapped, which may occur with foreclosure. Parents may find allowing adolescents the time and space to enter a moratorium before achieving a stable sense of identity difficult and referral for psychological consultation may occur.

**Intimacy vs Isolation**

The major psychosocial dilemma for people who have left adolescence is whether to develop an intimate relationship with another or move to an isolated position. People who do not achieve intimacy experience isolation. Isolated individuals have unique characteristics (Newman & Newman, 2003). Specifically, they overvalue social contact and suspect that all social encounters will end negatively. They also lack the social skills, such as empathy or affective self-disclosure, necessary for forming intimate relationships. These difficulties typically emerge from experiences of mistrust, shame, doubt, guilt, inferiority, alienation or role confusion associated with failure to resolve earlier developmental dilemmas and crises in a positive manner. A variety of social and contextual forces contribute to isolation. Our culture’s emphasis on individuality gives us an enhanced sense of separateness and loneliness. Our culture’s valuing of competitiveness (particularly among males) may deter people from engaging in self-disclosure. Men have been found to self-disclose less than women, to be more competitive in conversations and to show less empathy.

**Productivity vs Stagnation**

The midlife dilemma of is that of productivity versus stagnation. People who select and shape a home and work environment that fits with their needs and talents are more likely to resolve this dilemma by becoming productive. Productivity may involve procreation, work-based productivity or artistic creativity. Those who become productive focus their energy into making the world a better place for further generations. Those who fail to select and shape their environment to meet their needs and talents may become overwhelmed with stress and become burnt out, depressed or cynical on the one hand, or greedy and narcissistic on the other.

**Integrity vs Despair**

In later adulthood the dilemma faced is integrity versus despair. A sense of personal integrity is achieved by those who accept the events that make
up their lives and integrate these into a meaningful personal narrative in a way that allows them to face death without fear. Those who avoid this introspective process or who engage in it and find that they cannot accept the events of their lives or integrate them into a meaningful personal narrative that allows them to face death without fear develop a sense of despair. The process of integrating failures, disappointments, conflicts, growing incompetencies and frailty into a coherent life story is very challenging and is difficult to do unless the first psychosocial crisis of trust versus mistrust was resolved in favour of trust. The positive resolution of this dilemma in favour of integrity rather than despair leads to the development of a capacity for wisdom.

**Immortality vs Extinction**

In the final months of life the dilemma faced by the very old is immortality versus extinction. A sense of immortality can be achieved by living on through one’s children; through a belief in an afterlife; by the permanence of one’s achievements (either material monuments or the way one has influenced others); by viewing the self as being part of the chain of nature (the decomposed body becomes part of the earth that brings forth new life); or by achieving a sense of experiential transcendence (a mystical sense of continual presence). When a sense of immortality is achieved the acceptance of death and the enjoyment of life, despite frailty, becomes possible. This is greatly facilitated when people have good social support networks to help them deal with frailty, growing incompetence and the possibility of isolation. Those who lack social support and have failed to integrate their lives into a meaningful story may fear extinction and find no way to accept their physical mortality while at the same time evolving a sense of immortality.

Erikson’s model has received some support from a major longitudinal study (Valliant, 1977). However, it appears that the stages do not always occur in the stated order and often later life events can lead to changes in the way in which psychosocial dilemmas are resolved.

It is important for therapists to have a sensitivity to the personal dilemmas faced by family members who participate in marital and family therapy. The individual lifecycle model presented here and summarised in Table 1.7 offers a framework within which to comprehend such persona dilemmas.

**SEX-ROLE DEVELOPMENT**

One important facet of identity is sex role (Vasta, Haith & Miller, 2003). This area deserves particular consideration because a sensitivity to gender issues is essential for the ethical practice of family therapy. From birth
to five years of age, children go through a process of learning the concept of gender. They first distinguish between the sexes and categorise themselves as male or female. Then they realise that gender is stable and does not change from day to day. Finally they realise that there are critical differences (such as genitals) and incidental differences (such as clothing) that have no effect on gender. It is probable that during this period they develop gender scripts, which are representations of the routines associated with their gender roles. On the basis of these scripts they develop gender schemas, which are cognitive structures used to organise information about the categories male and female (Levy & Fivush, 1993).

Extensive research has shown that in western culture sex-role toy preferences, play, peer group behaviour and cognitive development are different for boys and girls (Serbin, Powlishta & Gulko, 1993). Boys prefer trucks and guns. Girls prefer dolls and dishes. Boys do more outdoor play with more rough and tumble, and less relationship-oriented speech. They pretend to fulfil adult male roles, such as warriors, heroes and firemen. Girls show more nurturant play involving much relationship conversation and pretend to fulfil stereotypic adult female roles, such as homemakers. As children approach the age of five years they are less likely to engage in play that is outside their sex role. A tolerance for cross-gender play evolves in middle childhood and diminishes again at adolescence. Boys play in larger groups, whereas girls tend to limit their group size to two or three.

There are some well-established gender differences in the abilities of boys and girls (Halpern, 2000). Girls show more rapid language development than boys and earlier competence at maths. In adolescence, boys competence in maths exceeds that of girls and their language differences even out. Males perform better on spatial tasks than girls throughout their lives.

While an adequate explanation for gender differences on cognitive tasks cannot be given, it is clear that sex-role behaviour is influenced by parents’ treatment of children (differential expectations and reinforcement) and by children’s response to parents (identification and imitation) (Serbin et al., 1993). Numerous studies show that parents expect different sex-role behaviour from their children and reward children for engaging in these behaviours. Boys are encouraged to be competitive and activity oriented. Girls are encouraged to be cooperative and relationship oriented. A problem with traditional sex roles in adulthood is that they have the potential to lead to a power imbalance within marriage, an increase in marital dissatisfaction, a sense of isolation in both partners and a decrease in father involvement in child care tasks (Gelles, 1995).

However, rigid sex roles are now being challenged and the ideal of androgyny is gaining in popularity. The androgynous youngster develops both male and female role-specific skills. Gender stereotyping is less marked in families where parents’ behaviour is less sex typed; where both
parents work outside the home; and in single-parent families. Gender stereotyping is also less marked in families with high socioeconomic status (Vasta et al., 2003).

**GAY AND LESBIAN LIFECYCLES**

A significant minority of individuals have gay or lesbian sexual orientations. When such individuals engage in family therapy, it is important that frameworks unique to their sexual identity be used to conceptualise their problems, rather than frameworks developed for heterosexual people and families (Laird, 2003).

**Gay and Lesbian Identity Formation**

Lifecycle models of the development of gay and lesbian identities highlight two significant transitional processes: self-definition and ‘coming out’ (Laird, 2003; Laird & Green, 1996; Malley & Tasker, 1999; Stone-Fish & Harvey, 2005; Tasker & McCann, 1999). The first process – self-definition as a gay or lesbian person – occurs initially in response to experiences of being different or estranged from same-sex heterosexual peers and later in response to attraction to and/or intimacy with peers of the same gender. The adolescent typically faces a dilemma of whether to accept or deny the homoerotic feelings he or she experiences. The way in which this dilemma is resolved is in part influenced by the perceived risks and benefits of denial and acceptance. Where adolescents feel that homophobic attitudes within their families, peer groups and society will have severe negative consequences for them, they may be reluctant to accept their gay or lesbian identity. Attempts to deny homoerotic experiences and adopt a heterosexual identity may lead to a wide variety of psychological difficulties including depression, substance abuse, running away and suicide attempts, all of which may become a focus for family therapy. In contrast, where the family and society are supportive and tolerant of diverse sexual orientations, and where there is an easily accessible supportive gay or lesbian community, then the benefits of accepting a gay or lesbian identity may outweigh the risks, and the adolescent may begin to form a gay or lesbian self-definition. Once the process of self-definition as gay or lesbian occurs, the possibility of ‘coming out’ to others is opened up. This process of coming out involves coming out to other lesbian and gay people; to heterosexual peers; and to members of the family. The more supportive the responses of members of these three systems, the better the adjustment of the individual.

In response to the process of ‘coming out’ families undergo a process of destabilisation. They progress from subliminal awareness of the young person’s sexual orientation, to absorbing the impact of this realisation and
adjusting to it. Resolution and integration of the reality of the youngster’s sexual identity into the family belief system depends on the flexibility of the family system, the degree of family cohesion and the capacity of core themes within the family belief system to be reconciled with the youngster’s sexual identity. Individual and family therapy conducted within this frame of reference, aim to facilitate the processes of owning homoerotic experiences, establishing a gay or lesbian identity and mobilising support within the family, heterosexual peer group, and gay or lesbian peer group for the individual.

**Gay and Lesbian Couple Lifecycles**

While there is huge variability in the patterns of lives of gay and lesbian couples, a variety of models of normative lifecycles have been proposed (Laird, 2003). Slater (1995) has offered a five-stage lifecycle model for lesbian couples. In the first stage of couple formation, the couple are mobilised by the excitement of forming a relationship but may be wary of exposing vulnerabilities. The management of similarities and differences in personal style so as to permit a stable relationship occurs in the second stage. In the third stage, the central theme is the development of commitment, which brings the benefits of increased trust and security and the risks of closing down other relationship options. Generativity, through working on joint projects or parenting, is the main focus of the fourth stage. In the fifth and final stage the couple learn to cope jointly with the constraints and opportunities of later life, including retirement, illness and bereavement on the one hand, and grandparenting and acknowledging life achievements on the other.

McWhirter and Mattison (1984) developed a six-stage model for describing the themes central to the development of enduring relationships between gay men. The first four stages, which parallel those in Slater’s model, are ‘blending’, ‘nesting’ ‘maintaining’ and ‘building’. McWhirter and Mattison argue that the fifth stage, which they term ‘releasing’, in the gay couple lifecycle is characterised by each individual within the couple pursuing his own agenda and taking the relationship for granted. This gives way to a final stage or ‘renewal’, in which the relationship is once again privileged over individual pursuits.

Research on children raised by gay and lesbian couples shows that the adjustment and mental health of children raised in such families does differ significantly from that of children raised by heterosexual parents (Laird, 2003).

Difficulties in managing progression through the lifecycle stages may lead gay and lesbian couples to seek family therapy (Coyle & Kitzinger, 2002; Green & Mitchell, 2002; Laird & Green, 1996; Stone-Fish & Harvey, 2005).
CLASS, CREED AND COLOUR

The models of family and individual development and related research findings presented in this chapter have all been informed by a predominantly western, white, middle-class, Judeo-Christian sociocultural tradition. However, in westernised countries, we now live in multicultural, multiclass context. A significant proportion of clients who come to family therapy are from ethnic minority groups. Also, many clients are not from the affluent middle classes, but survive in poverty and live within a subculture that does not conform to the norms and values of the white, middle-class community. When such individuals engage in family therapy, a sensitivity to these issues of race and class is essential (Falicov, 1995, 2003; Hardy & Laszlof, 2002; Ingoldby & Smith, 2005; McGoldrick, 2002).

This type of sensitivity involves an acceptance that different patterns of organisation, belief systems, and ways of being in the broader sociocultural context may legitimately typify families from different cultures. Families from different ethnic groups and subcultures may have differing norms and styles governing communication, problem-solving, rules, roles and routines. They may have different belief systems involving different ideas about how family life should occur, how relationships should be managed, how marriages should work, how parent–child relationships should be conducted, how the extended family should be connected, and how relationships between families and therapists should be conducted. Most importantly, family therapists must be sensitive to the relatively economically privileged position that most therapists occupy with respect to clients from ethnic minorities and lower socioeconomic groups. We must also be sensitive to the fact that we share a responsibility for the oppression of minority groups. Without this type of sensitivity we run the risk of illegitimately imposing our norms and values on clients and furthering this oppression.

SUMMARY

Families are unique social systems insofar as membership is based on combinations of biological, legal, affectional, geographic and historical ties. In contrast to other social systems, entry into family systems is through birth, adoption, fostering or marriage, and members can leave only by death. It is more expedient to think of the family as a network of people in the individual’s immediate psychosocial field. The family lifecycle may be conceptualised as a series of stages, each characterised by a set of tasks family members must complete to progress to the next stage. Failure to complete tasks may lead to adjustment problems. In the first two stages of family development, the principal concerns are with differentiating from the family of origin by completing school, developing relationships outside the family, completing one’s education and
beginning a career. In the third stage, the principal tasks are those associated with selecting a partner and deciding to marry. In the fourth stage, the childless couple must develop routines for living together, which are based on a realistic appraisal of the other’s strengths, weaknesses and idiosyncrasies. In the fifth stage, the main task is for couples to adjust their roles as marital partners to make space for young children. In the sixth stage, which is marked by children’s entry into adolescence, parent–child relationships require realignment to allow adolescents to develop more autonomy. The demands of grandparental dependency and midlife re-evaluation may compromise parents’ abilities to meet their adolescents’ needs for the negotiation of increasing autonomy. The seventh stage is concerned with the transition of young adult children out of the parental home. During this stage, the parents are faced with the task of adjusting to living as a couple again, to dealing with disabilities and death in their families of origin and of adjusting to the expansion of the family if their children marry and procreate. In the final stage of this lifecycle model, the family must cope with the parents’ physiological decline and approaching death, while at the same time developing routines for benefiting from the wisdom and experience of the elderly.

Family transformation through separation, divorce and remarriage may also be viewed as a staged process. In the first stage, the decision to divorce occurs and accepting one’s own part in marital failure is the central task. In the second stage, plans for separation are made. A cooperative plan for custody of the children, visitation, finances and dealing with families of origin’s response to the plan to separate must be made if positive adjustment is to occur. The third stage of the model is separation. Mourning the loss of the intact family; adjusting to the change in parent–child and parent–parent relationships; preventing marital arguments from interfering with interparental cooperation; staying connected to the extended family; and managing doubts about separation are the principal tasks at this stage. The fourth stage is the post-divorce period. Here couples must maintain flexible arrangements about custody, access and finances without detouring conflict through the children; retain strong relationships with the children; and re-establish peer relationships. Establishing a new relationship occurs in the fifth stage. For this to occur, emotional divorce from the previous relationship must be completed and a commitment to a new marriage must be developed. The sixth stage of the model is planning a new marriage. This entails planning for cooperative coparental relationships with ex-spouses and planning to deal with children’s loyalty conflicts involving natural and step-parents. It is also important to adjust to the widening of the extended family. In the final stage of the model, establishing a new family is the central theme. Realigning relationships within the family to allow space for new members and sharing memories and histories to allow for integration of all new members are the principal tasks of this stage.
The development of individual identity, within a family context, may also be conceptualised as a series of stages. At each stage the individual must face a personal dilemma. The ease with which successive dilemmas are managed is determined partly by the success with which preceding dilemmas were resolved and partly by the quality of relationships within the individual's family and social context. The dilemmas are: trust vs mistrust; autonomy vs shame and doubt; initiative vs guilt; industry vs inferiority; group identity vs alienation; identity vs role confusion; intimacy vs isolation; productivity vs stagnation; integrity vs despair; and immortality vs extinction.

Lifecycle models of the development of gay and lesbian identities highlight two significant transitional processes: the process of self-definition as a gay or lesbian person and the process of coming out to other lesbian and gay people, to heterosexual peers, and to members of the family. The more supportive the responses of others, the better the adjustment of the individual. Stage models for the development of lesbian and gay couple relationships have been developed which take account of their unique life circumstances.

When working with individuals from ethnic minorities and lower socioeconomic groups in family therapy, a sensitivity to issues of race and class is essential if the illegitimate imposition of norms and values from the dominant culture is to be avoided.
