In gastroenterological practice, patients commonly present complaining of abdominal pain. The clinician’s role is to undertake a full history and examination, in order to discern the most likely diagnosis and to plan safe and cost-effective investigation. This chapter describes an approach to this process. The underlying diagnoses and pathological mechanisms encountered in chronic pain are often quite different from those seen in acute pain, and for this reason each is considered in turn here.

Chronic abdominal pain

Anatomy and physiology of abdominal pain

Pain within the abdomen can be produced in two main ways: irritation of the parietal peritoneum or disturbance of the function and/or structure of the viscera (Box 1.1). The latter is mediated by autonomic innervation to the organs, which respond primarily to distension and muscular contraction. The resulting pain is dull and vague. In contrast, chemical, infectious or other irritation of the parietal peritoneum results in a more localised, usually sharp or burning pain. The location of the pain correlates more closely with the location of the pathology and may give important clues as to the diagnosis. However, once peritonitis develops, the pain becomes generalised and the abdomen typically becomes rigid (guarding).

Referred pain occurs due to the convergence of visceral afferent and somatic afferent neurons in the spinal cord. Examples include right scapula pain related to gallbladder pain and left shoulder region pain from a ruptured spleen or pancreatitis.

Clinical features

History taking

Initially the approach to the patient should use open-ended questions aimed at eliciting a full description of the pain and its associated features. Useful questions or enquiries include:

- ‘Can you describe your pain for me in more detail?’
- ‘Please tell me everything you can about the pain you have and anything you think might be associated with it.’
- ‘Please tell me more about the pain you experience and how it affects you.’

Only following a full description of the pain by the patient should the history taker ask closed questions designed to complete the picture.

In taking the history it is essential to elucidate the presence of warning or ‘alarm’ features (Box 1.2). These are indicators that increase the likelihood that an organic condition underlies the pain. The alarm features guide further investigation.

Historical features that it is important to elicit include those in the following sections.

Onset

- Gradual or sudden? Pain of acute onset may result from an acute vascular event, obstruction of a viscus or infection. Pain resulting from chronic inflammatory processes and functional causes is more likely to be gradual in onset.
Chapter 1 Approach to the patient with abdominal pain

Frequency and duration

• Colicky pain (which progresses and remits in a crescendo–decrescendo pattern)? Usually related to a viscus (e.g. intestinal, renal and biliary colic), whereas constant intermittent pain may relate to solid organs (Box 1.3).

• How long has the pain been a problem? Pain that has been present for weeks is unlikely to have an acutely threatening illness underlying it and very longstanding pain is unlikely to be related to malignant pathology.

Location: Radiation or referral (Figure 1.1 right)

• Poorly localised? Usually related to a viscus (e.g. intestinal, renal and biliary colic).

• Located to epigastrum? Disorders related to the liver, pancreas, stomach and proximal small bowel (from the embryological foregut).

Character and nature

• Dull, crampy, burning or gnawing? Visceral pain: related to internal organs and the visceral peritoneum.

---

**Box 1.1 Character of visceral versus somatic pain**

**Visceral**
- Originates from internal organs and visceral peritoneum
- Results from stretching, inflammation or ischaemia
- Described as dull, crampy, burning or gnawing
- Poorly localised

**Somatic**
- Originates from the abdominal wall or parietal peritoneum
- Sharper and more localised

---

**Box 1.2 Alarm features precluding a diagnosis of irritable bowel syndrome (IBS)**

**History**
- Weight loss
- Older age
- Nocturnal wakening
- Family history of cancer or IBD

**Examination**
- Abnormal examination
- Fever

**Investigations**
- Positive faecal occult blood
- Anaemia
- Leucocytosis
- Elevated ESR or CRP
- Abnormal biochemistry

---

**Box 1.3 Characteristic causes of different patterns of abdominal pain**

**Chronic intermittent pain**

- Mechanical:
  - Intermittent intestinal obstruction (hernia, intussusception, adhesions, volvulus)
  - Gallstones
  - Ampullary stenosis

- Inflammatory:
  - Inflammatory bowel disease
  - Endometriosis/endometritis
  - Acute relapsing pancreatitis
  - Familial Mediterranean fever

- Neurological and metabolic:
  - Porphyria
  - Abdominal epilepsy
  - Diabetic radiculopathy
  - Nerve root compression or entrapment
  - Uraemia

- Miscellaneous:
  - Irritable bowel syndrome
  - Non-ulcer dyspepsia
  - Chronic mesenteric ischaemia

**Chronic constant pain**

- Malignancy (primary or metastatic)
- Abscess
- Chronic pancreatitis
- Psychiatric (depression, somatoform disorder)
- Functional abdominal pain

- Located centrally? Disorders related to the small intestine and proximal colon (from the embryological midgut).

- Located to suprapubic area? Disorders related to the colon, renal tract and female reproductive organs (from the embryological hindgut).

Radiation of pain may be useful in localising the origin of the pain. For example, renal colic commonly radiates from the flank to the groin and pancreatic pain through to the back. Referred pain (Figure 1.1 left) occurs as a result of visceral afferent neurons converging with somatic afferent neurons in the spinal cord and sharing second-order neurons. The brain then interprets the transmitted pain signal to be somatic in nature and localises it to the origin of the somatic afferent, distant from the visceral source.
• **Sharp, pricking?** Somatic pain: originates from the abdominal wall or parietal peritoneum (Box 1.1).

One process can cause both features, the classic example being appendicitis, which starts with a poorly localised central abdominal aching visceral pain; as the appendix becomes more inflamed and irritates the parietal peritoneum, it progresses to sharp somatic-type pain localised to the right lower quadrant.

**Exacerbating and relieving features**

Patients should be asked if there are any factors that ‘bring the pain on or make it worse’ and conversely ‘make the pain better’. Specifically:

- **Any dietary features, including particular foods or the timing of meals?** Patients with chronic abdominal pain frequently attempt dietary manipulation to treat the pain. Pain consistently developing soon after a meal, particularly when associated with upper abdominal bloating and nausea or vomiting, may indicate gastric or small intestinal pathology or sensitivity.
- **Relief of low abdominal pain by the passage of flatus or stool?** This indicates rectal pathology or increased rectal sensitivity.
- **The effect of different forms of analgesia or anti-spasmodic when used may give clues as to the aetiology of the pain.** Simple analgesics such as paracetamol may be more effective in treating musculoskeletal or solid organ pain, whereas antispasmodics such as hyoscine butylbromide (Buscopan) or mebeverine may be more beneficial in treating pain related to hollow organs.
- **Pain associated with twisting or bending?** More likely related to the abdominal wall than intra-abdominal structures.
- **Pain severity** may be affected by stress in functional disorders, but increasing evidence shows that psychological stress also plays a role in the mediation of organic disease, such as inflammatory bowel disease (IBD).
Any associated symptoms?
The presence of associated symptoms may be instrumental in localising the origin of the pain.

- **Relationship to bowel habit: frequency, consistency, urgency, blood, mucus and any association of changes in the bowel habit with the pain are important.** Fluctuation in the pain associated with changes in bowel habit is indicative of a colonic process and is typical of irritable bowel syndrome (IBS).

- **Vomiting or upper abdominal distension?** Suggestive of small bowel obstruction or ileus.

- **Haematuria?** Indicates renal colic.

- **Palpable lump in the area of tenderness?** Suggests an inflammatory mass related to transmural inflammation of a viscus, but may simply be related to colonic loading of faeces.

### Examination technique

The physical examination begins with a careful general inspection.

- **Does the patient look unwell?** Obvious weight loss or cachexia is an indicator of malabsorption or undernourishment.

- **Is the patient comfortable? If in acute pain, are they adopting a position to ease the pain?** The patient lying stock still in bed with obvious severe pain may well have peritonitis, whereas a patient moving about the bed, unable to get comfortable, is more likely to have visceral pain such as obstruction of a viscus.

- **Observation of the skin** may demonstrate jaundice, pallor associated with anaemia, erythema ab igne (reticular erythematous hyperpigmentation caused by repeated skin exposure to moderate heat used to relieve pain) or specific extraintestinal manifestations of disease (Table 1.1). Leg swelling may be an indicator of decreased blood albumin related to liver disease or malnutrition.

- **Observe the abdomen** for visible abdominal distension (caused by either ascites or distension of viscus by gas or fluid).

- **Vital signs, including the temperature,** should be noted.

- **Examination of the hands** may reveal clues to intra-abdominal disease. Clubbing may be related to chronic liver disease, IBD or other extra-abdominal disease with intra-abdominal consequences. Pale palmar creases may be associated with anaemia. Palmar erythema, asterixis, Dupytren’s contractures and spider naevi on the arms may be seen in chronic liver disease.

- **Inspection of the face** may reveal conjunctival pallor in anaemia, scleral yellowing in jaundice, or periorbital corneal arcus indicating hypercholesterolaemia and an increased risk of vascular disease or pancreatitis.

- **Careful cardiac and respiratory examinations** may reveal abnormalities associated with intra-abdominal disease. For example, peripheral vascular disease may indicate that a patient is at risk for intestinal ischaemia; congestive heart failure is

associated with congestion of the liver, the production of ascites and gut oedema; and pain from cardiac ischaemia or pleuritis in lower-lobe pneumonia may refer to the abdomen.

- **Examination of the gastrointestinal (GI) system per se** begins with careful inspection of the mouth with the aid of a torch and tongue depressor. The presence of numerous or large mouth ulcers or marked swelling of the lips may be associated with IBD. Angular stomatitis occurs in iron deficiency. Glossitis may develop in association with vitamin B₁₂ deficiency caused by malabsorption.

- **Examination of the thyroid is followed by examination of the neck and axilla for lymphadenopathy.**

- **Careful inspection of the abdomen is repeated and the abdominal examination is completed as described in Part IV, taking great care to avoid causing undue additional discomfort.** The examiner must be careful to ask first whether there are any tender spots in the abdomen before laying on a hand. Special care should be taken, starting with very light palpation, asking the patient to advise the examiner of any discomfort felt and by watching the patient’s expression at all times. Only if light palpation is tolerated in an area of the abdomen should deep palpation be undertaken in that area. A useful additional sign to elicit when areas of localised tenderness are found is Carnett’s sign. While the examiner palpates over the area of tenderness, the patient is asked to raise their head from the bed against the resistance provided by the examiner’s free hand on their forehead. If the palpation tenderness continues or intensifies during this manoeuvre, it is likely to be related to the abdominal wall rather than to intra-abdominal structures.

### Approach to differential diagnosis of pain and directed investigation

Following a careful history and examination, the clinician should be able to develop an idea of which organ(s) is/are likely to be involved and what the likely pathogenesis might be considering the demographics of the patient and the nature of the pain. It is important to list the most likely diagnoses based on these factors first. The differential can then be expanded by the application of a surgical sieve (as described in Part IV) to add the less likely possibilities.

Most patients should have a minimal blood panel to rule out warning features and to make any obvious diagnoses. These would include full blood count (FBC); urea, creatinine and electrolytes; liver function tests (LFTs); and coeliac antibodies, especially if there is any alteration of bowel habit. Further testing should be directed at each of the most likely diagnoses in the list of differential diagnoses. The clinician should attempt to choose the range of investigations that will most cost-effectively examine for the greatest number of likely diagnoses with the greatest sensitivity and specificity (see Clinical example 1.1).

### Clinical Example 1.1

**History** Ms AP is a 37-year-old woman who describes 1 year of intermittent right lower quadrant abdominal pain. She is Caucasian, her body mass index is 19 kg/m² and she smokes 20 cigarettes/day. The pain first came on following an illness associated with vomiting and diarrhoea. She saw her GP and was given antibiotics, but stool culture revealed no pathogens. The diarrhoea settled spontaneously and she currently opens her bowels three times a day to soft-to-loose stool with no blood or mucus. The pain is aching and intermittent, but seems to be worse during periods of life stress. It often occurs about half an hour after meals and is associated with abdominal bloating and on occasion nausea, but no vomiting. It lasts 30 minutes to some hours at a time. There is no position in which she can get comfortable and she describes herself as ‘writhing around’ with the pain. She has reduced the size of her meals and avoids excess fibre, which seems to help. No specific foods contribute to the symptoms. Opening her bowels does not relieve the pain. She has trialled no medications. She has lost 5 kg in weight in the last year. The pain does not wake her at night and there is no nocturnal diarrhoea. There has been no change in the menstrual cycle and no association of the pain with menses. There has been no haematuria and she has never passed stones with the urine. She is on no regular medication. There is no significant family history.

**Examination** Observation reveals a thin woman with no hand or face signs of gastrointestinal disease; in particular, no pallor, skin lesions, angular stomatitis, mouth ulceration or tongue swelling. The abdomen is
Acute abdominal pain

The patient presenting with acute abdominal pain is a particular challenge to the clinician. Pain production within the abdomen is such that a wide range of diagnoses can present in an identical manner. However, a thorough history and examination still constitute the cornerstone of assessment. It is essential to have an understanding of the mechanisms of pain generation. Equally, it is important to recognise the alarm symptoms and initial investigative findings that help to determine which patients may have a serious underlying disease process, who therefore warrant more expeditious evaluation and treatment.

Clinical features

History taking

The assessment of the patient with abdominal pain proceeds in the same way whatever the severity of the pain; however, in the acute setting, assessment and management may need to proceed simultaneously and almost invariably involve consultation with a surgeon. Much debate has centred on the pros and cons of opiate analgesia in patients with severe abdominal pain, as this may affect assessment. The current consensus is that while judicious use of opiate analgesia may affect the examination findings, it does not adversely affect the outcome for the patient and is preferable to leaving a patient in severe pain.
The history (Table 1.3) gives vital clues as to the diagnosis and should include questions regarding the location (Figure 1.2), character, onset and severity of the pain, any radiation or referral, any past history of similar pain, and any associated symptoms.

Careful exclusion of past or chronic health problems that may have progressed to, or be associated with, the current condition is important. A patient with chronic dyspepsia may now be presenting with perforation of a duodenal ulcer. The patient with severe peripheral vascular disease, or who has had recent vascular intervention, might have acute mesenteric ischaemia. A binge drinker with past episodes of alcohol-related pain is at risk for acute pancreatitis, as is the patient with known cholelithiasis. Patients with past multiple abdominal surgeries are at risk for intestinal obstruction.

Questioning regarding current and past prescribed, illicit and complementary medicine use is necessary. The patient using non-steroidal anti-inflammatory drugs (NSAIDs) is at risk of peptic ulceration; use of anticoagulants increases the risk of haemorrhagic conditions; prednisone or immunosuppressants may blunt the inflammatory response to perforation or peritonitis, resulting in less pain than expected.

The Examination

Initial assessment is aimed at determining the seriousness of the illness. A happy, comfortable-appearing patient rarely has a serious problem, unlike one who is anxious, pale, sweaty or in obvious pain. Vital signs, state of consciousness and other indications of peripheral perfusion must be evaluated.

- **Examination of the non-abdominal organ systems** is aimed at determining any evidence for an extra-abdominal cause for the pain:
  - Abdominal wall tenderness and swelling with rectus muscle haematoma. Extremely tender, sometimes red and swollen scrotum with testicular torsion.
  - Resolving (sometimes completely resolved) rash in post-herpetic pain.
  - Ketones on the breath in diabetic ketoacidosis.
  - Pulmonary findings in pneumonia and pleuritis.
Examination of the abdomen focuses on the detection of peritonitis, any intra-abdominal masses or organomegaly, and localisation of the underlying pathology:
- Distension of the abdomen may be associated with intestinal obstruction.
- Bruising at the flanks (Grey Turner’s sign) and periumbilically (Cullen’s sign) is occasionally seen in acute haemorrhagic pancreatitis.
- Absent bowel sounds is indicative of ileus and in the presence of severe pain suggests peritonitis.
- High-pitched or overactive bowel sounds might indicate intestinal obstruction.

Palpation should start with very light examination well away from the area of greatest pain. Guarding, rigidity and rebound indicate peritoneal irritation. Guarding is a slow and sustained involuntary contraction of the abdominal muscles, rather than the flinching that is observed with sensitive or anxious patients. Careful exclusion of hernias at the inguinal canals and over surgical scars, as well as pelvic and rectal examination, is essential.

Investigation

Most patients will have an FBC, urea, creatinine and electrolytes, and dipstick urinalysis performed, although the results from these tests are neither sensitive nor specific. Serum lipase, however, is useful in detecting acute pancreatitis. It is essential that erect chest and abdomen and supine abdominal X-rays are performed when there is the possibility of intestinal perforation or obstruction. If the patient cannot sit up, the left lateral position may be used.

Modern imaging can detect the underlying pathology in acute abdominal pain with high sensitivity and specificity. While ultrasound examination has the benefits of portability and avoidance of radiation exposure, it is most useful in detecting disease of the
gallbladder, and gynaecological and obstetric conditions. CT has emerged as the dominant imaging tool for evaluation of the patient with severe acute abdominal pain. This has come about with the frequent advent of easy access to helical CT within or adjacent to the emergency department. The proper execution and interpretation of CT in this setting have been shown to reduce the need for exploratory laparotomy and hence morbidity, mortality and medical expense.
Management and prognosis

The management and prognosis of both acute and chronic abdominal pain very much depend on the underlying cause. The management and prognosis of the individual diseases that cause abdominal pain (see Box 1.3 and Figure 1.2) are dealt with in each of the individual disease chapters of this book (Chapters 7 to 30).

KEY POINTS

- Peritoneal pain localizes to the area affected, whereas visceral pain tends to be felt in the upper abdomen – foregut; central abdomen – midgut; or lower abdomen – hindgut.
- Mode of onset, time course, location and radiation, character and exacerbants/relievers are essential to determining the cause of abdominal pain.
- Symptoms associated with the pain are invaluable in further localising the disease process.
- Develop a wide-ranging list of differential diagnoses first, then tailor the investigative strategy to that list and other factors that affect the individual patient.

SELF-ASSESSMENT QUESTION

(The answer to this question is given on p. 265)

A 45-year-old woman presents acutely with vague, cramping, right upper quadrant, epigastric and right shoulder blade pain. She has experienced similar pain on a few previous occasions over the last year, but never this severe. In the past the pain has been exacerbated by fatty meals, as on this occasion. She cannot get comfortable with the pain; it tends to come in waves but never completely abates. When it is present she finds breathing more difficult. She has taken paracetamol with minimal relief.

With regard to your initial approach to this patient, which of the following is most true?

(a) The localisation of her pain to one area indicates that there is irritation of the parietal peritoneum.
(b) Her scapular pain indicates that there is retroperitoneal involvement.
(c) Her description of the pain makes a hollow organ the likely source.
(d) The epigastric and right upper quadrant location of her pain indicate that it is likely to be coming from the midgut.
(e) She is describing radiation of the pain to the back, which makes a pancreatic cause more likely.
